

# Non-functional requirements

- raising awareness

Targeted Extended Delivery Centre

Nordea  
Group IT  
IT Strategy, Architecture and Methodology  
Agile Methods, Tools and Support  
Project Academy, March 2015

*Making it possible*

## Comments regarding the training material to EDC

- This material is a “self-study-package” especially targeted to the EDC consultants in India
- The aim is primarily to raise the awareness of the importance of non-functional requirements
- Handing out slides from the original presentation without any kind of speech or comments from one of the instructors is not our recommended way of working
- Thus to fulfil the need of a “self-study-package” to EDC, each slide is accompanied with notes to explain the main points

## Why spend time on non-functional requirements?

- Insufficient non-functional requirements may lead to a system that works according to the functional requirements but there is a risk of:
  - Poor response time which makes the system inefficient to use
  - Loss of data which makes it difficult to trust the result delivered by the system
  - In-efficient user interface that makes the system difficult to use
  - Increased costs due to less availability than expected
  - Serious implications due to not fulfilling legal regulations

There is a lot of focus on non-functional requirements at the moment.

**Non-functional requirements are important because they may drive a system's foundations - in other words, its architecture.** Because these requirements are system-wide, they are by definition extremely important. In addition, they can be more significant than the functional requirements specified in use cases.

**Gathering non-functional requirements is hard to do, and yet it is really important!**

## By improving the non-functional requirements we aim at

- Saving money
  - System architecture is designed from the beginning to meet the requirements
- Increasing quality and customer satisfaction
  - Avoid unstable applications in our production environments – and thus avoid unhappy customers and bad publicity
  - Detailed non-functional requirements are a way of making quality measurable

We might just as well be honest and admit the reasons (mentioned on the slide) for focusing more on non-functional requirements than earlier.

## Non-functional requirements in an agile project

- Working with non-functional requirements are equally important no matter what approach you have to the development work!
- In an agile project non-functional requirements have to be defined in the very beginning of a project to secure the right architecture

**Defining non-functional requirements  
should be done very early in the lifecycle of an agile project!**

You might be thinking: “We are working agile, so this is not relevant for us”. But you are so wrong!

Working with non-functional requirements are equally important no matter what approach you have to the development work!

It will be very expensive if you have to change the architecture later on during the project lifecycle.

**Requirements derives from  
needs or opportunities!**

## Requirements derive from needs or opportunities

- Needs are based on a problem or opportunity
- In order to fulfil the stakeholder needs a system must offer certain product features (or services)
- Software requirements describe the functionality and the quality of the product features

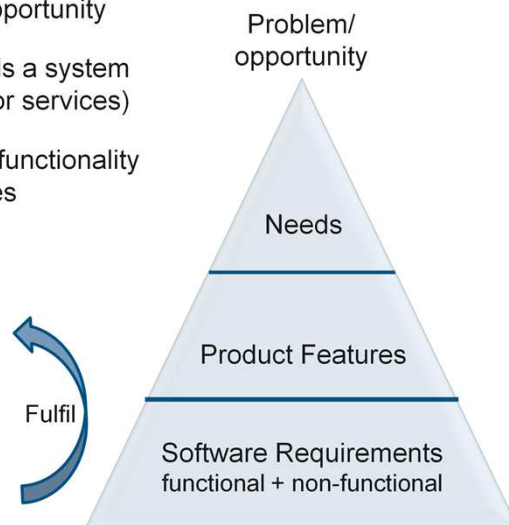

Ex.:

Problem or opportunity:

**Trading with securities**

Product features:

- The system must use secure communication channels for payment transactions.
- The system must be able to handle increased number of transactions without decreased performance.
- The system must calculate rates and prices with high accuracy.

Nordea

7 •

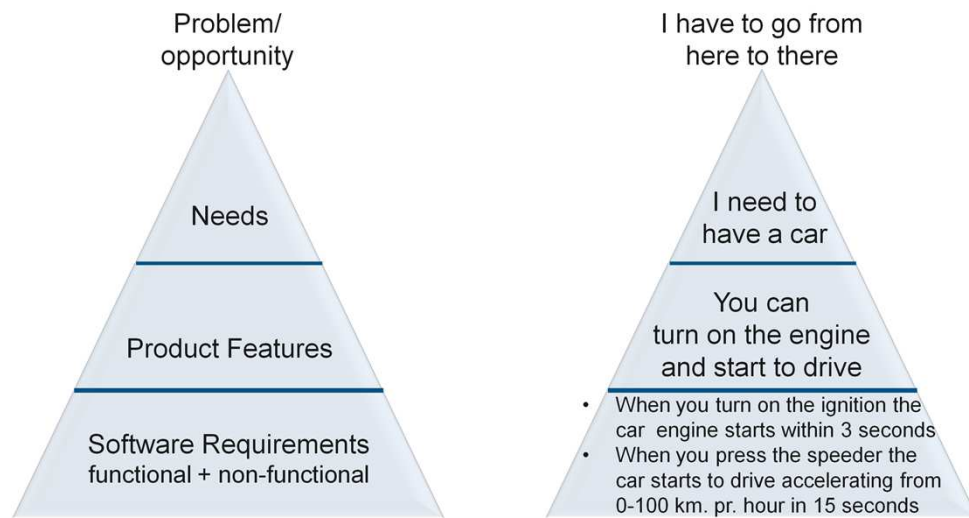

It is important to keep in mind that all system requirements – functional as well as non-functional – derive from some kind of stakeholder's need. And the needs are caused by a problem or a business opportunity. No requirement should be "invented" – they are all based on stakeholder needs.

### The example

Trading with securities is a need and the product features listed are offered to fulfil the need.

The product features are not yet specific enough to be software requirements.

## An example

The pyramid to the left shows the "model" – the pyramid to the right shows an example.

**What are non-functional requirements?**

**Functional versus non-functional requirements**

Functional requirement

Non-functional requirement

Requirements impact design, architecture and test

## What are non-functional requirements?

- Non-functional requirements are requirements that do *not* relate to functionality, but to attributes such as reliability, efficiency, usability, maintainability and portability
- Non-functional requirements also state constraints of a system

**Non-functional requirements must be stated clearly and be measurable**

Constraints can also be seen as limitations.

An example of a constraint: A certain development process must be followed.

Sometimes you hear other terms for non-functional requirements:

- Supplementary requirements
- Quality requirements or
- Quality requirements and constraints

In Nordea the term non-functional requirements covers **quality requirements and constraints**.

Just like functional requirements non-functional requirements must be stated clearly and be measurable!

## Functional versus non-functional requirements

### Functional requirement

- Specifies *what* a component or system must perform
- Defines specific behaviour or function

### Non-functional requirement

- Specifies the quality and constraints of a component or system

**Requirements impact design, architecture and test**

- All requirements have impact on the system design
- The non-functional requirements impact mainly on system architecture
- Both functional and non-functional requirements have to be tested

In this and the following slides we will see some examples that hopefully will help you understand the difference between functional requirements and non-functional requirements.

Depending of the non-functional requirements certain hardware might be required to be able to handle the desired performance.

The non-functional requirements have impact on design, architecture and test.  
Testing non-functional requirements requires more than testing functional requirements – skills, knowledge, competences, tools, etc.

## Functional versus non-functional requirements

### Functional requirement

- When you turn on the ignition the car engine starts
- When you press the speeder the car starts to drive

### Non-functional requirement

- When you turn on the ignition the car engine starts within 3 seconds
- When you press the speeder the car starts to drive accelerating from 0-100 km. pr. hour in 15 seconds
- The car must be able to seat 4 persons
- The car must be able to drive off road

Car # 1

Car # 2

Car # 3

All the cars can fulfil the functional requirements.  
Only Car # 3 can fulfil all the requirements.

## Functional versus non-functional requirements – Examples

### Functional requirement

Sweden:  
The system allows the user to log in to Netbank by entering the personal identification number and response code

### Non-functional requirement

All Nordea countries:  
Netbank is available for the users 24/7 except during a planned two-hour maintenance window the last Sunday each month between 2-4 a.m.

2000 users must be able to log in to Netbank at the same time. The system should be available for use for all users within maximum 3 seconds

Requirements impact design, architecture and test

In Nordea we might have extra complexity due to different solution in some countries depending on the local laws in the different countries. Here is an example of different log-on procedures.

“Available 24/7” is a **reliability** requirement.

“2000 users” is a **performance** requirement.

## Functional versus non-functional requirements – Examples

### Functional requirement

The user should be able to move between the overview, check balance and register payment pages

### Non-functional requirement

The system must support use of keyboard, mouse and short-cut keys in all user operations

Requirements impact design, architecture and test

The functional requirements state that the user must be able to move around within the different parts of the system.

The non-functional requirements state the different possibilities for doing so.

The non-functional requirement is a **usability** requirement.

## Functional versus non-functional requirements – Examples

### Functional requirement

Not applicable

### Non-functional requirement

- The system must support the browsers: Firefox version x.x, Internet Explorer version x.x and Safari version x.x
- The system must encrypt all external communications using the RSA algorithm

Requirements impact design, architecture and test

These non-functional requirements are examples of **constraints**.

(RSA is an algorithm for public-key cryptography).

Note: There might also be requirements that are neither functional nor non-functional system requirements but are still very important requirements for the project to fulfil – even though they are not software requirements.

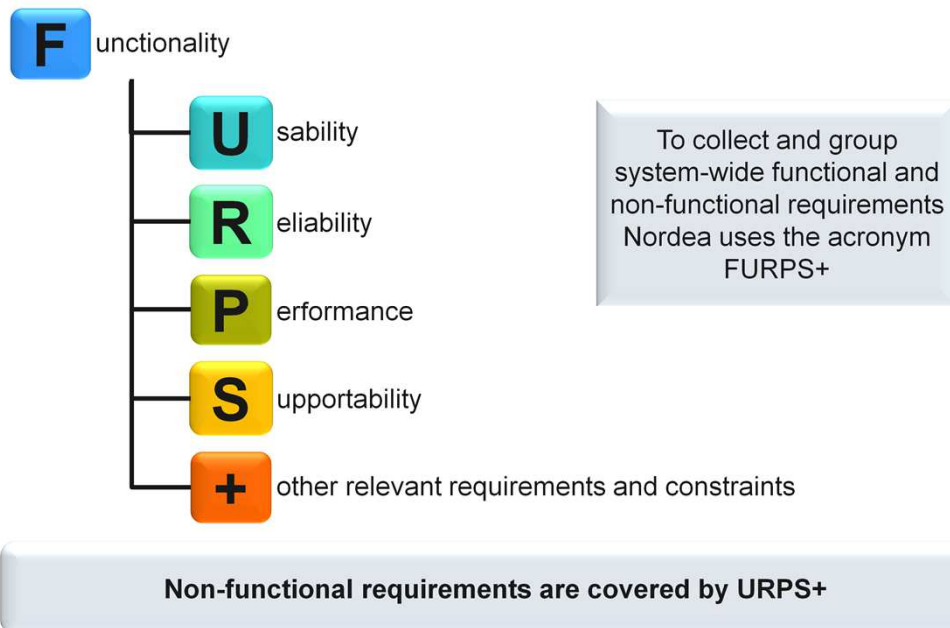

**What is FURPS+?**

**Inclusive a lot of examples**

**Model for  
categorizing  
requirements**

## Categorizing requirements - FURPS+

In Nordea FURPS+ is the chosen model for categorizing requirements.

FURPS+ are used for categorizing all kinds of requirements.

URPS+ are the non-functional requirements.

URPS are quality requirements, + is constraints.

The categories are primarily meant as a support in remembering or finding all requirements.

Meaning: What category the different requirements belong to is not so important. What is important is to find them all.

We will talk a lot more about these categories on the following slides.

## What is FURPS+?

### Functionality

- Functional requirements are most often documented in use cases
- Functional requirements relevant for more than one use case are documented in the Supplementary Specification – where the non-functional requirements are also described
- Examples of sub-categories within functionality:
  - Reporting - What kind of reports (monthly, weekly, daily) are required?
  - Auditing - Which actions in the system should be logged and how?
  - Printing - Is there a standard print layout that is required?
  - Security - Should all users have the same access rights?
  - Licensing - Which licenses are required?
  - Online help - What kind of online help is required throughout the system?

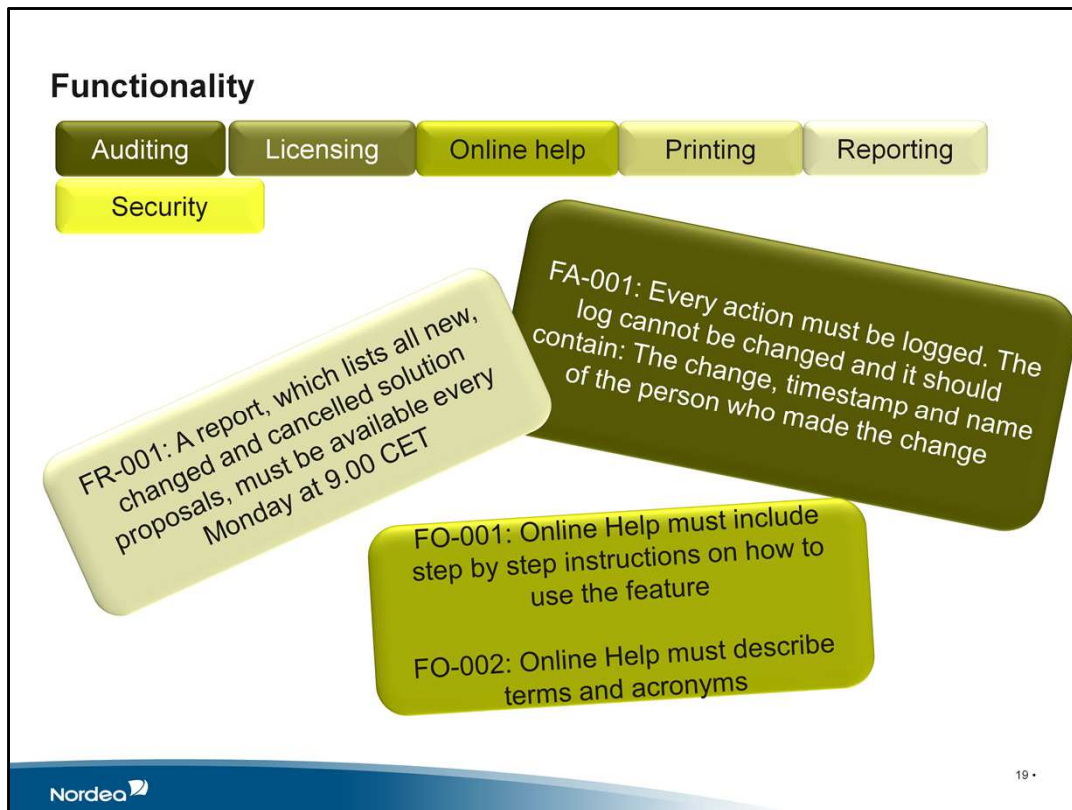

The F in the FURPS+ acronym represents all the system-wide functional requirements that we would expect to see described. These usually represent the main product features that are familiar within the business domain of the solution being developed.

**The system wide functional requirements can be very technically oriented.** This is another reason why people have trouble capturing them and stating them as requirements - people may be very familiar with the business domain concepts, but not so familiar with technology concepts.

Functional requirements that you may consider to be also **architecturally significant system-wide functional requirements may also include**

- **localization**
- **mail**
- **system management**
- **workflow**

Each of these may represent functionality of the system being developed and they are each a system-wide functional requirement.

Many of the functional requirements are documented in use cases, however some are not applied to a specific use case. Therefore they should be included in the Supplementary Specification.

**Requirements should have unique IDs** in order to increase traceability. **The abbreviation can be decided within each project.** What we have used here is only an example of what the IDs could be like.

FR - Functionality Reporting  
FA - Functionality Auditing  
FO - Functionality Online Help

All examples – on requirements in this category and the others - are taken from the Supplementary Specification Guidelines.

## What is FURPS+?

### Usability

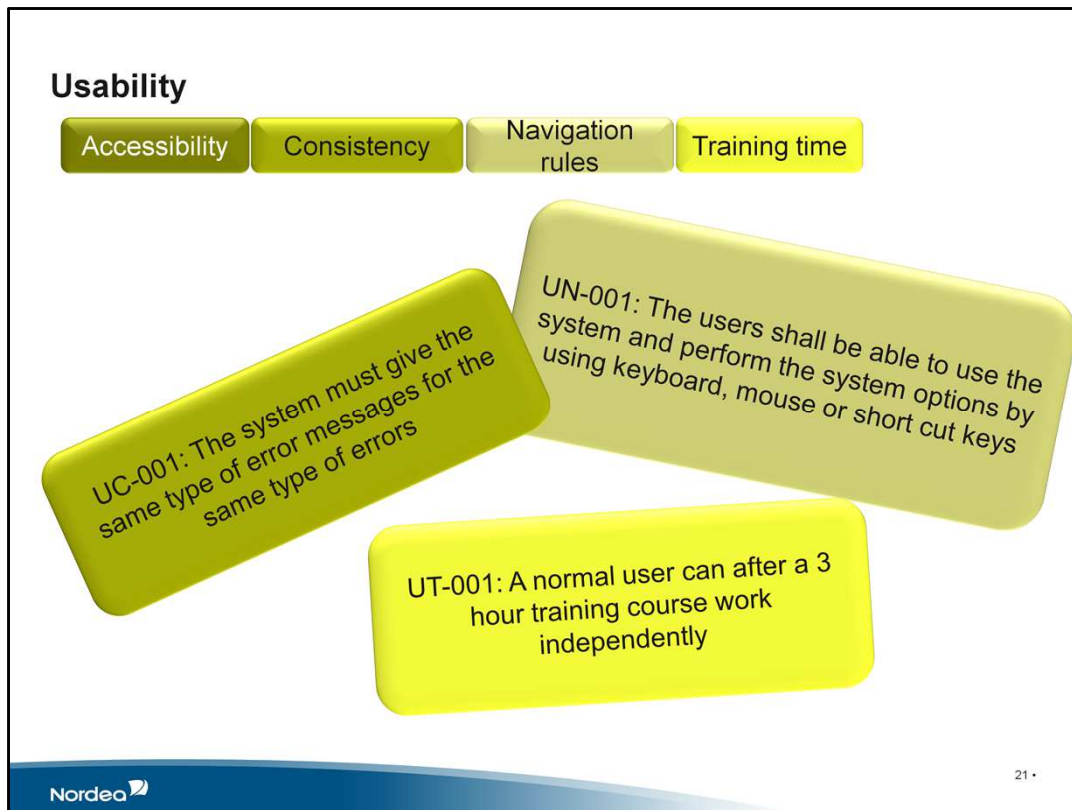

The capability of a software to be understood, learned, used and liked by its users

- Examples of sub-categories within usability:
  - Accessibility - Which browser is required?
  - Consistency - Are the requirements free of contradicting statements?
  - Navigation rules - Which rules exist regarding navigation between different pages?
  - Training - What training do the users need before they are productive?

Usability is about how easy it is for the users to use the system. This can be tested by having real users trying to use the system and report the users behaviour.

Consistency covers the degree of uniformity, standardization and freedom from contradiction among the documents or parts of component or system.

Maybe it is necessary to have separate focus on usability – depending on what you are developing.

Training time – To be a “good” requirement a definition (or at least a common understanding) of what is meant by a “normal user” is required.

UC - Usability Consistency

UN - Usability Navigation rules

UT - Usability Training time

## What is FURPS+?

### Reliability

The ability of the software product to perform its required functions under stated conditions for a specified period of time, or for a specified number of operations

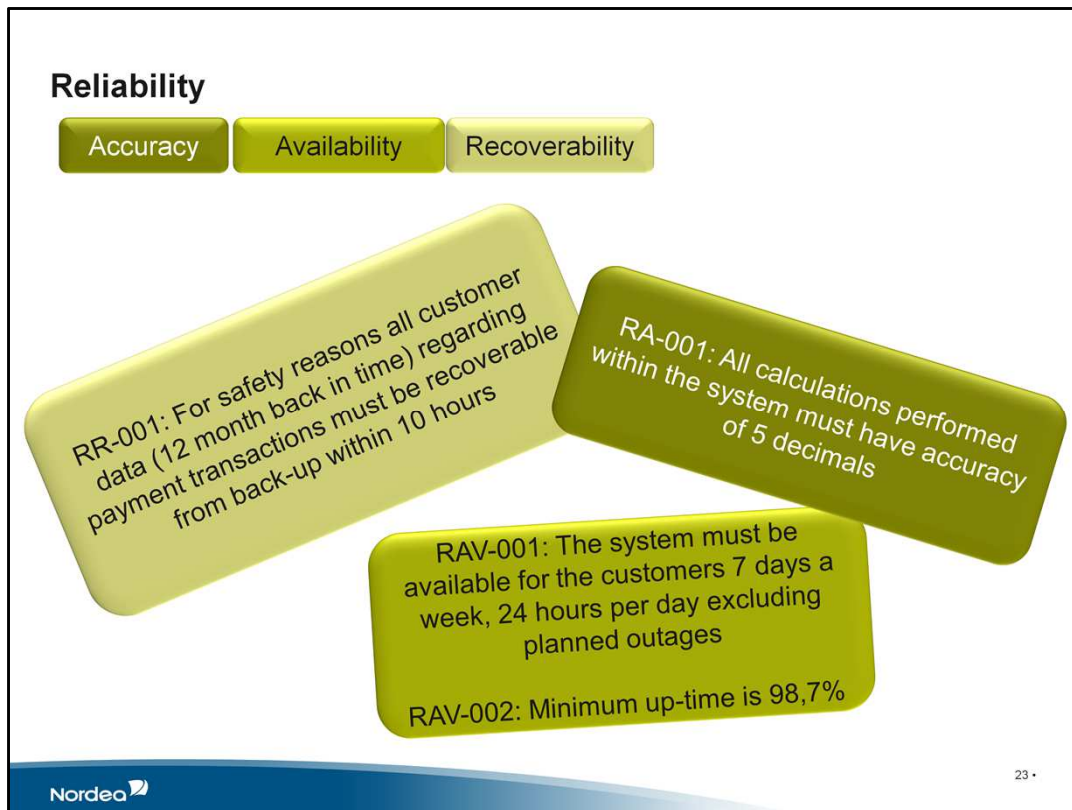

- Examples of sub-categories within reliability:
  - Availability (robustness) - What is the required up-time, Mean Time Between Failure?
  - Accuracy - What is the needed degree of precision?
  - Recoverability - How should the system recover from a failure?

Availability means the degree to which a component or system is operational and accessible when required for users. Often expressed as percentage.

Mean Time Between Failure is usually written as MTBF.

Accuracy means the capability of the software product to provide the right or agreed results or effects with the needed degree of precision.

Recoverability means the capability of the software product to re-establish a specified level of performance and recover the data directly affected in case of failure. E.g. if a break down should happen during money transfer what data must not be lost.

Accuracy – Even though the results of calculations are only shown on the screen with 2 decimals it might still be a requirement that all calculations should be done with 5 decimals.

Availability - Some requirements might imply requirements not only to the software but also to hardware, surveillance, monitoring, SLA's etc.

In some situations it will be necessary to give the stakeholder stating the requirements an estimate of what it will require and cost to fulfil the requirements. Knowledge about the cost might make him lower the requirements regarding availability.

RA - Reliability Accuracy

RAV - Reliability Availability

RR - Reliability Recoverability

## What is FURPS+ ?

### Performance

The degree to which a system or component accomplishes its designated functions within given constraints regarding processing time and throughput rate

- Examples of sub-categories within performance:
  - Capacity - How many customers or transactions should the system accommodate?
  - Response time - How long time is a transaction allowed to take?
  - Throughput - What is the needed ability of the system to support a given flow of information?

This is the category that most people think of when they hear the term non-functional requirements!

## Performance

Throughput

Response time

Capacity

PT-001: The system shall handle 100 000 payment transactions on a peak hour

PT-002: 2000 users must be able to log in to Netbank at the same time

PR-001: The response times for the different functions shall at least fulfil the following response time requirements:

	Required response time (sec)	
End-user transaction	97,5% of transactions	99,5% of transactions
Login page	2	4
Start page	3	6

Response time – Requirements regarding response time is often described in tables like this.

When capturing requirements regarding response time keep in mind that the response time may be different from normal situations to peak hours.

PT - Performance Throughput

PR - Performance Response time

PC - Performance Capacity

## What is FURPS+ ?

### Supportability

How the system is installed, configured, monitored and how it identifies exceptions or faults. Supportability is also about how hardware and software maintenance is handled

Examples of sub-categories within supportability:

- Adaptability - What are the requirements to adapt to a new environment or upgrades?
- Compatibility - Which surrounding systems does the system need to be compatible with?
- Configurability - How should the system be configured?
- Install ability - What are the requirements regarding system installation?
- Localization - What are the requirements for supporting multiple languages?
- Scalability - How should the system be scaled up if the load increases?
- Testability - Is the software to be developed possible to test?
- Maintainability - How should the system be maintained?

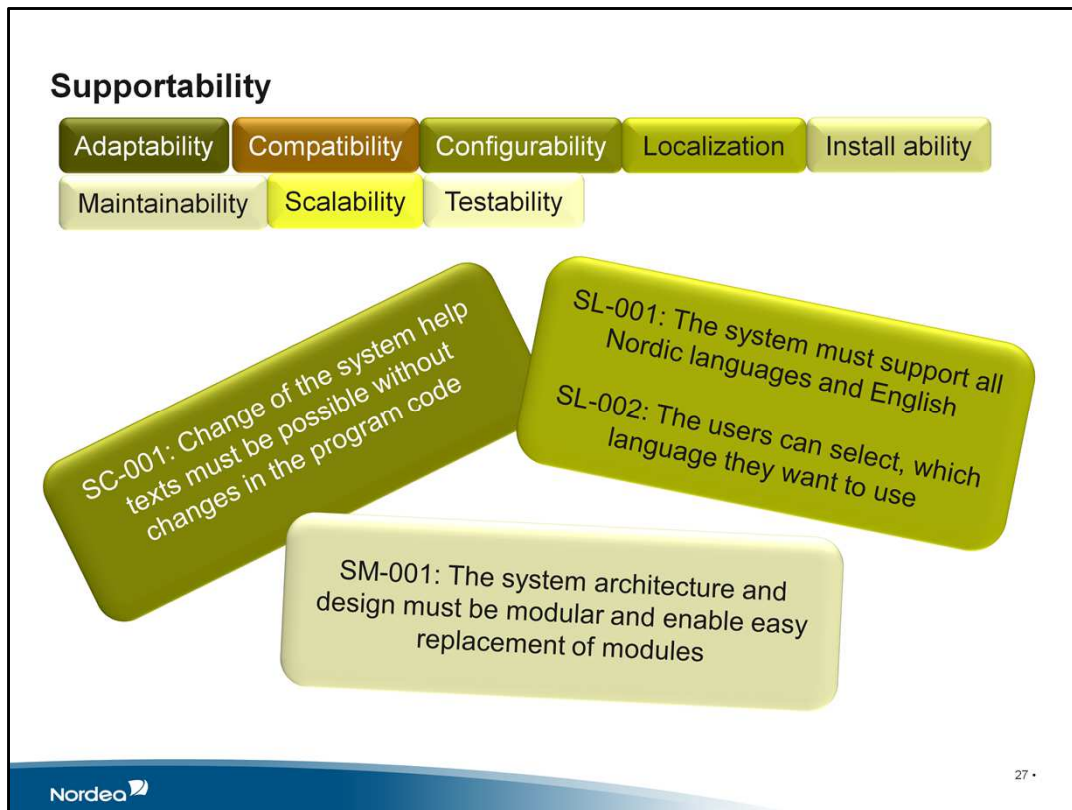

Supportability is the most technical oriented non-functional requirements category. That is probably the reason why a lot of business people find it the hardest to describe their requirements within this category.

Adaptability means the capability of the software product to be adapted for different specified environments. This without applying actions or means other than those provided for this purpose for the software considered.

Scalability means the capability of the software product to be upgraded to accommodate increased loads.

Testability means the capability of the software product to enable modified software to be tested.

Maintainability means the ease with which a software product can be modified to correct defects, modified to meet new requirements, modified to make future maintenance easier, or adapted to a changed environment.

**Compatibility** – It is important to find out if there are requirements on compatibility of this system with previous versions of the system or with legacy systems providing the same capability?

An example could be: The system web services should be back compatible at least one version.

**Scalability** – This can be regarding increased data volumes or number of users. What volumes of users and data will the system support? This may be expressed as a profile over time.

An example could be: If load in the system increases, it must be possible to add new hardware without changing program code.

**Testability** – An example could be: Subsystems should be possible to be tested separately using mock-ups simulating surrounding systems.

SC - Supportability Configurability

SL - Supportability Localization

SM - Supportability Maintainability

## What is FURPS+?

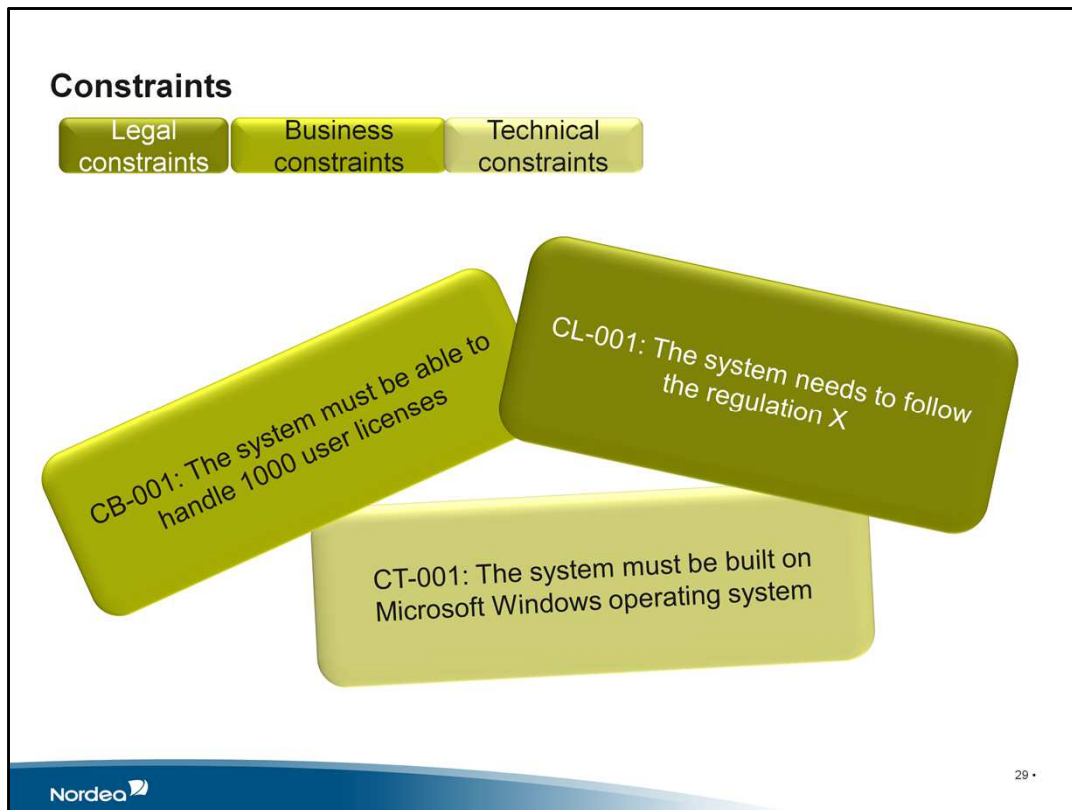

### Constraints (the +)

A statement of restriction that modifies a requirement (or set of requirements) by limiting the range of acceptable solutions

Examples of sub-categories within constraints:

- Legal, Copyright and Other Notices
  - Are there any legislation or warranties that affect the software?
- Business constraints
  - Are there any constraints on the mechanism used to provide licensing capacity?
- Technical constraints
  - Are there any constraints regarding what kind of hardware or operating systems to use?

If you look for descriptions of FURPS+ on the internet you might find different types of constraints like design constraints, implementation constraints, interface constraints, physical constraints. If it is relevant to use other or more types of constraints (sub categories) than the three listed on the slide, feel free to add them.

CL - Constraints Legal

CB - Constraints Business

CT - Constraints Technical

**The URPS+ categories are meant to help us remember all aspect of the non-functional requirements.** It is not so important what category the requirements are placed in. Therefore when capturing requirements do not spend too much time on categorizing the requirements.

**The Stakeholders  
of non-functional requirements**

## The stakeholders of non-functional requirements – 1 of 2

- Responsible Business Partners
  - Need for all requirements to be captured and described in order to harmonise expectations between key stakeholders
  - Approve the requirements
- Key Business Stakeholders
  - Contribute to the requirements
- Requirement Owner
  - Owner and manager of the requirement production baseline
- System Analyst (driver of requirements work)
  - Is responsible for capturing and describing all requirements in a change initiative
- Project Manager
  - Uses requirements to plan the project, prevent scope creep and for risk mitigation

A lot of different roles are involved in the work of capturing and/or documenting requirements – or they are dependant on the result of the requirement work.

### Key Business Stakeholders

Anyone from the business area giving input to the requirements can act as a Key Business Stakeholder.

The Key Business Stakeholders contribute to non-functional requirements mainly within Usability and Reliability and also system wide Functionality (not captured in use cases). They might need support from other project participants in order to see or understand the impact requirements have on the system to be and the cost it will be to fulfil them. But they are the ones deciding what the requirements should be.

### Requirement Owner

This is a new role in Nordea! It is described in the Requirements and Test Portal on the Nordea intranet.

The Requirement Owner is the owner and manager of the Requirement Production Baseline. If the system exists already and no baseline is set, it is the responsibility of the Requirement Owner to establish the Requirement Production Baseline.

The role as Requirement Owner can be assigned to anyone from the business area who has the most impact on the requirements.

**Requirement Production Baseline is a collection of the requirements that are currently in production.**

**Requirement Baseline is the new requirement work on-going.**

Requirement Baseline is a collection of requirement descriptions both functional and non-functional. First version is often established during a change initiative and handed over to maintenance when the IT deliveries are put into production thus becoming the first Requirement Production Baseline.

In Nordea we are working on having Requirement Production Baselines established for all applications – but it will take time...

### **System Analyst**

In SDP – System Development Process – the driver of the requirement work is called System Analyst. But sometimes the role is called IT Analyst, Senior Analyst or something else.

## Non-functional requirement stakeholders

- Software Architect
  - Contributes to non-functional requirements
  - Designs the system based on functional and non-functional requirements
- Developers and system maintenance resources
  - Contribute to non-functional requirements
  - Develop the system based on functional and non-functional requirements
- Test Manager
  - Test Manager and/or test resource(s) review both functional and non-functional requirements and approve testability
  - Is responsible for allocating needed functional and non-functional test resource(s) together with the Project Manager.
  - Is responsible for following up status of functional and non-functional tests
- Responsible IT Partner
  - Might have to be involved if there are hardware or performance issues to deal with

Software Architect

Developer

Test Manager

Responsible IT Partner

32

### Software Architect

Contributes to non-functional requirements mainly within Performance, Supportability and Constraints

### Developers and system maintenance resources

Contribute to non-functional requirements mainly within Performance, Supportability and Constraints

**How are non-functional requirements captured and documented?**

## How are non-functional requirements captured?

When defining non-functional requirements for a new or improved application you can conduct a **non-functional requirements workshop**.

Material to be used when facilitating the workshop is available on the portal called Step In.

The non-functional requirements workshop gives you a **kick-start** to the work of finding and describing non-functional requirements.

## How are non-functional requirements captured?

- Create a list of different types of non-functional requirements
  - For each non-functional requirement, formulate one or more questions
  - Assist the stakeholders by showing them potential impact of answering a question one way or the other
  - Capture the responses from the stakeholders to each question
  - Assign a priority or weighting to each response
- 
- See an example on the next slide

**The System Analyst is responsible for capturing requirements  
– a number of other roles contribute**

This is *one* way of doing it... You can see an example of this on the next slide.

The FURPS+ categorization can help retrieve the non-functional requirements.  
Remember all requirements should be based on stakeholder needs.

### Note:

Performance requirements for an existing system can be derived from measurements in production.

While creating performance requirements for a new system it sometimes is impossible to specify exact needed performance figures e.g. throughput of a component, or response time for a transaction. These requirements need to be collected during testing.

Needed resources: performance tester, developer and architect.

## How are non-functional requirements captured?

- Example of non-functional requirement questionnaire
  - The questionnaire template is called Supplementary Requirements Questionnaire and can be found in the Requirements and Test Portal on the Nordea intranet – as well as other templates to use when working with requirements

Non-functional requirement	Questions	Impact	Answers	Priority
Availability	Are there any requirements regarding the system "up time"? This may be specified in terms of mean Time Between Failures (MTBF)	The higher availability, longer time to market time.	Availability is a key product feature. The product must have a MTBF of 60 days.	High

**Adopt the language** in the questions to the persons that should answer them e.g. business, architecture.

## How are non-functional requirements documented?

- Non-functional requirements are documented in the Supplementary Specification or in the Software Requirements Specification
- A (non-functional) requirement should only be described in one place
- If a specific non-functional requirement is only applicable for a part of the system this should be stated in the description of the requirement
- Functional requirements relevant for more than one use case are also documented in the Supplementary Specification

Supplementary  
Specification

Software  
Requirements  
Specification

**In Nordea we have 2 different requirements documentation packages to choose from:**

1. **Use Cases and Supplementary Specification** - most beneficial when there is functionality to develop.
2. **Software Requirements Specification** - a traditional way of documenting and most beneficial when you have no functionality to develop or when functionality is already given, e.g. Batch, Commercial of the Shelf (COTS).

Projects that do not have a Supplementary Specification sometimes documents non-functional requirements in the System Architecture Document (SAD) which is *not* correct. Only links to requirement documents should be included in the SAD.

The **Supplementary Specification Guidelines** contains a lot of examples of non-functional requirements. These can be used as inspiration.

**Note:** System wide functional requirements are also documented in the **Supplementary Specification**.

## REQB Glossary

- When working with requirements it is recommended to use the REQB Glossary
- The glossary (vocabulary) defines a common standard for terms and expressions within Requirements Engineering
- Usage of the glossary ensures a common understanding of terms thus minimising misunderstandings
- Target group for the glossary is everyone working on or reading functional and non-functional requirements
  - Gathering requirements
  - Specifying requirements
  - Discussing requirements

**REQB = Requirements Engineering Qualifications Board**

REQB = **Requirements Engineering Qualifications Board** is a group of international experts who work together to set an international standard (common language) for Requirements Engineering.

There are many reasons why it is a good idea to use the REQB Glossary:

- A group using terms or expressions defined in the REQB glossary “speaks” the same language
- One common language within Requirements Engineering helps to prevent misunderstandings
- It is easy to double-check the meaning of a term/expression in the glossary in case of doubts. This means no time is spent on discussing what a term or expression means
- REQB is an international standard and it is used worldwide
- ISTQB (International Software Testing Qualifications Board) is used by Test in Nordea and these two standards and glossaries are aligned. So when the requirements resources use terms or expressions as defined in the REQB glossary, it is easier for the test resources to understand what is meant and vice versa
- The quality of the requirements is raised, which leads to lower development costs and higher probability of meeting deadlines

A few examples from REQB Glossary:

- **Baseline** is a specification or software product that has been formally reviewed or agreed upon, that thereafter serves as the basis for further development, and that can be changed only through a formal change control process
- **Constraint** is a statement of restriction that modifies a requirement or set of

requirements by limiting the range of acceptable solutions

- **Elicitation** is the act of obtaining information from other people. In the context of Requirements Engineering, elicitation is the process of gathering requirements from stakeholders
- **Functional requirement** is a requirement that specifies a function that a component or system must perform
- **Non-functional requirement** is a requirement that does not relate to functionality, but to attributes such as reliability, efficiency, usability, maintainability and portability

The REQB Glossary can be found via the Requirements & Test Portal in the Nordea Intranet.

**Note:**

Since REQB is a glossary/vocabulary, REQB does not replace SDP or any other development method but supports a method with a common standard language.

**Why is non-functional testing  
important?**

## Why is non-functional testing important?

- Non-functional testing gives an indication of how well the non-functional requirements are met, for example:
  - Is the system stable during expected load?
  - Are there any limitations/bottlenecks identified?
    - Where are the limits/bottlenecks?
  - How does the system react in an emergency situation?
  - Are all supported languages available?
  - Does the release have the same performance metrics as the last release?

**Testing contributes with vital information of whether the system is ready for production launch or not**

The result of the tests are basis for decision of whether or not to deploy to production.

## **What does it require to test non-functional requirements?**

- Functional and non-functional requirements have been reviewed and testability approved
- Production-like test data and test environments are in place
- Test tools, e.g. Quality Center (test management tool) and Load Runner (performance test tool) are in use – contact Development Tools team
- Test cases and test sets are created and planned
- Test resources with the right competences are available - contact Testing Services

**Review of requirements is an important part of testing.  
This also applies to non-functional requirements!**

Where can you find  
more information?

## Requirements in Step In

The screenshot illustrates the 'Requirements in Step In' portal. The top navigation bar includes 'Nordea', 'Step In', 'Knowledge areas', 'Tools', 'Community', and 'Teams'. The left sidebar shows 'Applications' (Administration, Customer, Tools) and 'SPIN' (Step In, Telefonbog, Uddannels). The central menu lists 'Management' (Project Management, Business Case Management, Programme Management) and 'Development' (Requirements, Test, SDP Framework). The main content area displays a 'Requirements' space with a diagram titled 'Requirements Lifecycle and Development' showing relationships between Agile Toolbox, SDP Toolbox, Craftsmanship, Non-Functional Requirements, Requirements Tools, Requirements Glossary, and UX/UI Design. The right sidebar contains sections for 'Join the Conversations', 'Upcoming Conferences and Seminars', and 'Contact'.

When you get your Nordea user-ID and password you will be able to find all the information regarding requirements, and see the templates, guidelines and examples etc. in the Step In portal.

Step In contains descriptions of methods, tools, support and training regarding project management and system development in Nordea.

In addition to the information you will also be able to read and join conversations and discussions about relevant topics.
